

Prices Tracker

Updated:
15 February, 2023

Consumer Price Index

When there is a change in prices, it affects the quantity of goods and services that can be purchased by a fixed income. Researchers take into account both the amount that can be bought with a unit of currency and the changes in item quality when measuring changes in prices. To understand the overall changes in prices for a specific group such as consumers or manufacturers, researchers create a representative basket of relevant goods and services for the group and track the changes in the basket and its price over time. This results in a price index. The rate of inflation can then be calculated using the price index. One of the most frequently used methods of measuring inflation is to determine the 12-month percent change in the index values, which shows how prices in a particular month compare to prices from the same month one year earlier.

[Consumer prices](#) increased 6.4 percent over the year ending January 2023 , according to the Consumer Price Index for all urban consumers (CPI-U). The core CPI, which does not include the more-volatile food and energy prices, increased 5.6 percent over the same one-year period.

In January 2023, the annualized one-month change in the consumer price index (CPI) was 6.2 percent, following 1.6 percent in December 2022.

ALL STUFF DATA

In January 2023, housing prices contributed 3.5 percentage points to the CPI one-year inflation rate of 6.4 percent, far above the category's January 2022 contribution of 2.4 percentage points. Food prices added 1.4 percentage points to January 2023 inflation, substantially above the year-prior contribution of 0.9 percentage point. Transportation prices increased the inflation rate by 0.7 percentage point in the latest data, compared to 3.8 percentage points in January 2022. Energy prices increased the inflation rate by 0.7 percentage point in January 2023, far below the year-prior contribution of two percentage points. Medical care prices make up 8.5 percent of the CPI basket and contributed 0.3 percentage point to overall inflation in the latest data, in line with a contribution of 0.2 percentage point one year prior.

Inflation Expectations

Researchers acquire information on probable variations in prices by conducting frequent surveys of people and analyzing market information. One method based on market trends is called the [inflation breakeven](#) and is determined by comparing the return on a standard government bond to the return on a bond that is protected against inflation, both with the same maturity. The gap between these two yields represents the average level of inflation that the market anticipates for the duration of the bond. From FED: The breakeven inflation rate represents a measure of expected inflation derived from 5-Year Treasury Constant Maturity Securities (BC_5YEAR) and 5-Year Treasury Inflation-Indexed Constant Maturity Securities (TC_5YEAR). The latest value implies what market participants expect inflation to be in the next 5 years, on average.

To determine predicted inflation over the five years beginning in five years, we can utilize the market-based metric.Over this five-year period, markets suggest 2.2 percent inflation per year. Inflation rates in the near-term are therefore expected to exceed inflation rates in the longer-term
